Foreword

Manly Hydraulics Laboratory (MHL) is a business unit within the Water Group of the NSW Department of Climate Change, Energy, the Environment and Water. The NSW water level database has been developed to support a number of programs associated with coastal, floodplain and estuary management for the NSW Department of Climate Change, Energy, the Environment and Water – Conservation Programs, Heritage and Regulation. The monitoring service is available to NSW Government and other organisations across Australia.

This annual summary presents water level measurements captured by automatic water level recording stations along the coastal estuaries and rivers of NSW from 1 July 2023 to 30 June 2024. MHL maintains the automatic recording stations and catalogues the data collected.

Requests to access the data and further information should be directed to:

Executive Summary

The *NSW Estuary and River Water Level Annual Summary 2023–24* presents the results of water level monitoring obtained by the automatic recording stations along the coastal estuaries and rivers of New South Wales over the period 1 July 2023 to 30 June 2024.

During this period, the overall data capture across the network, excluding missing data and data outside of desired quality tolerances, was 97.6%. The target recovery rate of 95% is achieved for the 2023–24 reporting period.

This report contains:

- a brief description of the estuary and river water level measurement program
- guidelines of how to use this report and how to access the database
- a list of all stations for which MHL collected water level data in 2023–24 (**Table 4-2**)
- maps of station locations and the annual data summaries for each site
- **Appendix A** *,* which details the water level digitised continuous data and discrete historical data
- **Appendix B**, a glossary of terms
- **Appendix C**, a list of other publications which may be of interest
- **Appendix D**, data quality control process.

1 Water level monitoring program

The network of automatic recorders and the associated analysis routines enable efficient delivery of water level data. As well as near-real time water level information at over 220 stations in NSW, extracts from the historical database of water levels can be made available on request (refer to **Appendix A**).

The present program is based on a network of automatic water level recording stations installed at various coastal sites (see **Table 4-2** for station location maps). This network consists of over 220 permanent stations funded by the NSW Department of Climate Change, Energy, the Environment and Water – Conservation Programs, Heritage and Regulation (DCCEEW CPHR). All water level stations in this report are owned by DCCEEW CPHR with the exception of Ocean Street Bridge, Dee Why, Curl Curl, Riverview Parade and Queenscliff Bridge, which are owned by Northern Beaches Council.

The network features four distinctive systems of data capture: gas purge pressure system, solid state floatwell, submersible pressure transducer and ultrasonic/radar distance measuring units. The logging systems consist of data loggers which generally record water levels every 15 minutes, while some stations record at a 1-minute logging interval.

MHL's public website shows each station metadata with instrument and survey details, station characteristics and frequency distribution analysis result.

Water level data is transferred to MHL's collection, processing and storage system hosted on cloud computing platforms using telemetry techniques based on common Internet protocols and data connections over cellular telephone networks. Some stations are transferred directly to the Bureau of Meteorology (BoM) via Event-reporting Radio Telemetry System (ERTS).

The raw data is also transferred in a separate process to an MHL database hosted in NSW government data centres (GovDC) where it is subject to a quality assurance process involving several control steps to maintain data quality. Data is backed up daily and archived to long-term storage at regular intervals.

© Crown 2025

2 How to use this report and access the data

2.1 How to use this report

The NSW coastal zone is divided into geographic regions based on river systems to present water monitoring information. Location maps display the station locations and the annual plots confirm the availability and suitability of data for the particular period of interest.

All the data appearing in this report are recorded in Australian Eastern Standard Time (AEST). Allowance for daylight saving time has not been made.

A list of water level data collected and stored is included in **Appendix A**. Digitised continuous water level data is tabulated in **Table A1**, whilst discrete historical water level data (mainly from staff gauge readers) is tabulated in **Table A2**.

Once a choice has been made of the period for which information is required, data and services can be obtained in a variety of formats, according to their intended use.

2.2 Data provision and access

MHL provides a full online data access service via the internet for its clients, and a limited access service for the general public at http://www.mhl.nsw.gov.au.

Typically, the last seven days of data are available online in a non-quality controlled form to aid the fastest possible access to raw data records. The online service for clients can provide access to all data catalogued in **Appendix A**.

Quality controlled data may be ordered via the MHL web page (http://www.mhl.nsw.gov.au), by emailing data-request@mhl.nsw.gov.au, or via customised decision support tools that can be provided on request.

Water level data is provided to the public on behalf of DCCEEW CPHR through the following methods:

- the public webpages of MHL, DCCEEW CPHR and BoM, providing near real-time access to a limited sample of data
- a web-based data request system where electronic requests can be submitted via MHL's homepage at http://www.mhl.nsw.gov.au under the *Data Request* menu
- a web-based self-serve portal has been developed to allow specific users to download data or access a web services application for automated data self-service. Contact MHL to obtain a user name and password, visit https://www.mhl.nsw.gov.au/MHLFIT for more information.

Water level data is provided to DCCEEW CPHR and the NSW State Emergency Service (SES) through the following methods:

- DCCEEW CPHR and SES officers access a password-protected customised MHL web portal, providing near-real time environmental data and the 'quality assured' historical database
- SES officers receive automated notifications for flood warning systems
- API data feeds and 3rd party dashboards are provided for some SES units.

© Crown 2025

Data access continues to assist the BoM, Crown Lands, local government authorities, SES, NSW Police, WaterNSW, NSW Surf Life Saving Association, universities, the NSW court system, private consultancies and Transport for NSW.

Please note, all water level data is available in Australian Height Datum (AHD) via the DCCEEW CPHR password-protected customised MHL web portal and the MHL public web page, with the exception of local water resource datum and assumed datum stations. Data users should take care to confirm the datum of any data obtained prior to use.

© Crown 2025

3 Significant events

There were no major flood warnings issued by the BoM during 2023-24 for the NSW coast, with only minor to moderate flood warnings issued in 2024.

In January 2024, minor to moderate flood warnings were issued by the BoM for the Tweed River, with a minor flood warning issued for the Bellinger River. In April 2024, minor to moderated flood warnings were issued for the Hawkesbury River, minor flood warnings were issued for the Kalang River, Hastings River, Cooks River, and Georges River. In June 2024, minor to moderate flood warnings were issued for the Hawkesbury River, minor flood warnings were issued for the Cooks River, Georges River, and Sussex Inlet.

Table 3-1 lists the 2023–24 flood warnings as described by the SES's NSW flood classification system.

Table 3-1 2023–24 flood warnings

River/estuary system	Date	NSW SES classification
Tweed River	Jan 2024	Minor to Moderate
Bellinger River	Jan 2024	Minor
Kalang River	April 2024	Minor
Hastings River	April 2024	Minor
Hawkesbury River	April 2024	Minor to Moderate
	June 2024	Minor to Moderate
Cooks River	April 2024	Minor
	June 2024	Minor
Georges River	April 2024	Minor
	June 2024	Minor
Sussex Inlet	June 2024	Minor

The SES determines flood warning classifications based on the following definitions:

Minor flooding: Causes inconvenience. Low-lying areas next to watercourses are inundated, which may require the removal of stock and equipment. Minor roads may be closed and low-level bridges submerged.

Moderate flooding: In addition to the above, the evacuation of some houses may be required. Main traffic routes may be covered. The area of inundation is substantial in rural areas, requiring the removal of stock.

Major flooding: In addition to the above, extensive rural areas and/or urban areas are inundated. Properties and towns are likely to be isolated and major traffic routes likely to be closed. Evacuation of people from flood-affected areas may be required.

4 Water level monitoring summary

4.1 Data capture performance

Water level data presented by MHL is collected and analysed through a quality assurance process in accordance with MHL's internal standards and work instructions, as described in **Appendix D**. This process results in a quality code which is assigned to all water level data, as described in **Table 4-1**. Access to site and time specific station records, with quality codes is described in **Section 2**.

During 2023–24, the overall data capture across the network, for data with a quality code of 162 or better, was 97.6%. **Table 4-2** Index of figures provides data capture percentages for each river and estuary network. Missing data or data where the indication of measurement uncertainty is greater than ±0.05 metres can result in gaps in the data record. This can be caused by a range of reasons, such as sensor or equipment damage or failure, power failure, or site specific environmental issues such as siltation or collapse of waterway banks at monitoring stations.

Automatic recorded water level data is typically recorded to a resolution that is higher than the overall measurement uncertainty. A sensor may record data to three decimal places (measured in metres). However, due to combined measurement uncertainties involved in the collection of the data and environment influences, overall measurement uncertainty is typically to two decimal places (measured in metres). These uncertainties are accounted for through quality control and quality assurance processes.

Table 4-1 DCCEEW CPHR data quality code descriptions

Quality code		Water level*
55	Records processed to	±0.02 m
100	Data from previous MHL database, processed to	±0.02 m
105	Records processed to	±0.05 m
150	Uncoded – data not yet quality controlled	Raw data from the instrument with only preliminary quality checks performed
161, 162	Dry sensor	Sensor out of water with flow/with no flow
208	Records processed to greater than	>±0.05 m
1, 204, 205, 206, 207, 255	Data loss/data missing	

* A quality code is assigned based on infield status verification checks, survey and instrument calibrations including *an indication* of measurement uncertainty. Site specific measurement uncertainty estimates with defined confidence limits can be quantified using statistical techniques on request.

4.2 Interpretation of data

There are various factors which can influence water level data in the extensive network of automated water level recorders operated and maintained by MHL. Differences between sites can be attributed to the characteristics of the overall water body being analysed, and also characteristics specific to the station locality and design.

© Crown 2025

Report MHL2971 *NSW Water Level Frequency Distribution Analysis* (Feb 2025) provides a statistical analysis and frequency distribution analysis of available water level information for the majority of water level stations. Stations are classified into one of three station types:

1. Ocean tide stations ('O', dominated by a semi-diurnal tide).
2. Estuary stations ('E', particularly intermittently closed and open lakes and lagoons (ICOLLs), generally having a reduced tidal influence, and may experience both flood conditions and static water levels, governed by entrance morphology).
3. Flood stations ('F', characterised by their position along the river and the effect rainfall has on the river conditions. These stations can be tidally influenced or non-tidal such as sites upstream of a weir or floodgate).

It is recommended the reader reviews this report and becomes familiar with relevant environmental conditions for the station of interest to assist interpretation of water level data.

Refer to report MHL3065 *NSW Ocean and River Entrance Tidal Levels and Air Pressure Annual Summary 2023–24*, for annual water level data at ocean tide classified sites.

4.3 Water level monitoring summary

This section documents locality maps and quality assured water level monitoring summaries for each station. **Table 4-2** provides an index to the figures presented.

^ Data capture percentages do not include ocean tide stations

AHD	Australian Height Datum (1971)
CTF	Cease to Flow of control structure
AD	Assumed Datum
LWRD	Local Water Resources Datum

Estuary water level readings are available in AHD with the exception of Logans Crossing and Mount George, which are in the local water resources datum (LWRD); Kooroowi and

© Crown 2025

Ashlea Bridge Downstream, which are in an assumed datum (AD); and Woolgoolga which is using Cease to Flow of control structure (CTF) as gauge zero. There are a number of estuary level gauges that still maintain level data in the local port datum, which generally equates to Indian Springs Low Water (ISLW). An indicative adjustment from the AHD level to local datum is shown in **Table 4-3**. AHD levels were calculated circa 1990 for MHL by NSW Public Works Survey, using the range ratio method and tidal harmonic analysis over varying time periods. Please note that AHD levels are revised from time to time and improvements to GPS surveying techniques may provide additional refinement.

Table 4-3 Summary of adjustment from AHD to local datum

River/estuary	Station	Local datum *	Adjustment AHD (1971) to local datum
Cobaki Broadwater	Cobaki	TRHD (1963)	+0.863

Appendix B Glossary of terms

The following glossary of terms defines common terms used across MHL publications referenced in Appendix C.

Amplitude (H)	One-half of the difference in height between consecutive high water and low water, hence half the tide range.
Automatic tide gauge	An instrument that automatically registers the rise and fall of the tide. In some instruments, the registration is accomplished by recording the heights at regular time intervals in digital format.
Benchmark (BM)	A fixed physical object or mark used as reference for a vertical datum. A tidal benchmark is one near a tide station to which the tide staff and tidal datums are referred. A primary benchmark is the principal (or only) mark of a group of tidal benchmarks to which the tide staff and tidal datums are referred.
Chart datum	The datum to which soundings on a chart are referred. It is usually taken to correspond to a low-water elevation, and its depression below mean sea level is represented by the symbol Z.
Constituent	One of the harmonic elements in a mathematical expression for the tide-producing force and in corresponding formulas for the tide or tidal current. Each constituent represents a periodic change or variation in the relative positions of the earth, moon and sun. A single constituent is usually written in the form y = A cos (at + á), in which *y* is a function of time as expressed by the symbol *t* and is reckoned from a specific origin. The coefficient *A* is called the amplitude of the constituent and is a measure of its relative importance. The angle (at + á) changes uniformly and its value at any time is called the phase of the constituent. The speed of the constituent is the rate of change in its phase and is represented by the symbol a in the formula. The quantity *a* is the phase of the constituent at the initial instant from which the time is reckoned. The period of the constituent is the time required for the phase to change through 360° and is the cycle of the astronomical condition represented by the constituent.
Digital Recorder (or logger)	An electronic recorder system which stores the information in accessible form, for example, on tape or solid state memory.
Digitise	To translate analog information into digital form i.e. a series of numeric data readable by, and stored within, a digital computer.
Diurnal	Having a period or cycle of approximately one tidal day. Thus, the tide is said to be diurnal when only one high water and one low water occur during a tidal day, and the tidal current is said to be diurnal when there is a single flood and a single ebb period of a reversing current in the tidal day. A rotary current is diurnal if it changes its direction through all points of the compass once each tidal day. A diurnal constituent is one which has a single period in the constituent day. The symbol for such a constituent is the subscript *1*.
Encoder	A device that translates tidal movement into computer readable data.
Estuary	An embayment of the coast in which fresh river water entering at its head mixes with the relatively saline ocean water. When tidal action is

© Crown 2025

	the dominant mixing agent it is usually termed a tidal estuary. Also, the lower reaches and mouth of a river emptying directly into the sea where tidal mixing takes place. The latter is sometimes called a river estuary.
Extreme High Water	The highest elevation reached by the sea as recorded by a tide gauge during a given period.
Extreme Low Water	The lowest elevation reached by the sea as recorded by a tide gauge during a given period.
Floatwell	A stilling well in which the float of a float-actuated gauge operates.
Gas purged pressure gauge	A type of tide gauge in which gas, usually nitrogen, is emitted from a submerged tube at a constant rate. Fluctuations in hydrostatic pressure due to changes in tidal height modify the emission rate for recording.
Harmonic analysis	Process of measuring or calculating the relative amplitudes and frequencies of all the significant harmonic components present in a given wave form.
Harmonic prediction	Method of predicting tides by combining the harmonic constituents into a single tidal curve. The work is usually performed by electronic digital computer.
Head	The difference in water level at either end of a strait, channel, inlet, etc.
High Water (HW)	The maximum height reached by a rising tide. The high water is due to the periodic tidal forces and the effects of meteorological, hydrologic, and/or oceanographic conditions. For tidal datum computational purposes, the maximum height is not considered a high water unless it contains a tidal high water.
High water mark	A line or mark left upon tide flats, beach, or alongshore objects indicating the elevation of the intrusion of high water. The mark may be a line of oil or scum on alongshore objects, or a more or less continuous deposit of fine shell or debris on the foreshore or berm. This mark is physical evidence of the general height reached by wave runup at recent high waters. It should not be confused with the Mean High Water Line or Mean Higher High Water Line.
Higher High Water (HHW)	The highest of the high waters (or single high water) of any specified tidal day due to the declination A_l effects of the moon and sun.
Higher Low Water (HLW)	The highest of the low waters of any specified tidal day due to the declination A_l effects of the moon and sun.
Highest Astronomical Tide (HAT)	The highest level which can be predicted to occur under average meteorological conditions and under any combination of astronomical conditions; this level will not be reached every year. HAT is not the extreme level which can be reached as storm surges may cause considerably higher levels to occur.
Hydrographic datum	A datum used for referencing depths of water and the heights of predicted tides or water level observations. Same as *chart datum*. See *Datum*.
Indian Spring Low Water	A datum originated by Professor G. H. Darwin when investigating the tides of India. It is an elevation depressed below mean sea level by an amount equal to the sum of the amplitudes of the harmonic constituents M_2, S_2, K_1, and O_1.

© Crown 2025

Inverse barometer effect	The inverse response of sea level to changes in atmospheric pressure. A static reduction of 1.005 mb in atmospheric pressure will cause a stationary rise of 1 cm in sea level.
K_1	Lunisolar diurnal constituent. This constituent, with O_1, expresses the effect of the moon's declination. They account for diurnal inequality and, at extremes, diurnal tides. With P_1, it expresses the effect of the sun's declination. Speed = T + h = 15.041,068,6° per solar hour.
Lambda	Smaller lunar evectional constituent. This constituent, with V_2, U_2, and (S_2), modulates the amplitude and frequency of M_2 for the effects of variation in solar attraction of the moon. This attraction results in a slight pear-shaped lunar ellipse and a difference in lunar orbital speed between motion toward and away from the sun. Although (S_2) has the same speed as S_2, its amplitude is extremely small. Speed = 2T - s + p = 29.455,625,3° per solar hour.
Low Water (LW)	The minimum height reached by a falling tide. The low water is due to the periodic tidal forces and the effects of meteorological, hydrologic, and/or oceanographic conditions. For tidal datum computational purposes, the minimum height is not considered a low water unless it contains a tidal low water.
Lower High Water (LHW)	The lowest of the high waters of any specified tidal day due to the declination A_l effects of the moon and sun.
Lower Low Water (LLW)	The lowest of the low waters (or single low water) of any specified tidal day due to the declination A_l effects of the moon and sun.
Lowest Astronomical Tide (LAT)	The lowest level which can be predicted to occur under average meteorological conditions and under any combination of astronomical conditions; this level will not be reached every year. LAT is not the extreme level which can be reached as storm surges may cause considerably lower levels to occur.
Lunar tide	That part of the tide on the earth due solely to the moon as distinguished from that part due to the sun.
Magnetic tape	Recording tape on which (numeric) data may be stored.
M_2	Principal lunar semi-diurnal constituent. This constituent represents the rotation of the Earth with respect to the Moon. Speed = 2T - 2s + 2h = 28.984,104,2° per solar hour.
Mean High Water (MHW)	A tidal datum. The average of Mean High Water Spring and Mean High Water Neap.
Mean High Water Springs (MHWS), Mean Low Water Springs (MLWS)	The height of MHWS is the average, throughout a year when the average maximum declination of the moon is 23.5º, of the heights of two successive high waters during those periods of 24 hours (approximately once a fortnight) when the range of the tide is the greatest. The height of MLWS is the average height obtained by the two successive low waters during the same periods.
Mean High Water Neaps (MHWN), Mean Low Water Neaps (MLWN)	The height of MHWN is the average, throughout a year, as defined above, of two successive high waters during those periods of 24 hours (approximately once a fortnight) when the range of the tide is least. The height of MLWN is the average height obtained by the two successive low waters during the same periods.

© Crown 2025

Mean Range of Tide (Mn)	The difference in height between Mean High Water and Mean Low Water.
Modem	A device allowing a computer to be accessed over a telephone line.
Neap tides	Tides of decreased range or tidal currents of decreased speed occurring semi-monthly as the result of the moon being in quadrature. The neap range (Np) of the tide is the average range occurring at the time of neap tides and is most conveniently computed from the harmonic constants. It is smaller than the mean range where the type of tide is either semi-diurnal or mixed and is of no practical significance where the type of tide is predominantly diurnal. The average height of the high waters of the neap tide is called Neap High Water or High Water Neaps (MHWN) and the average height of the corresponding low waters is called Neap Low Water or Low Water Neaps (MLWN).
O_1	Lunar diurnal constituent. See K_1. Speed = T - 2s + h = 13.943,035,6° per solar hour.
Phase	1. Any recurring aspect of a periodic phenomenon, such as new moon, high water, flood strength, etc. 2. A particular instant of a periodic function expressed in angular measure and reckoned from the time of its maximum value, the entire period of the function being taken as 360°. The maximum and minimum of a harmonic constituent have phase values of 0° and 180°, respectively.
Pressure sensor	A pressure transducer sensing device for water level measurement. A relative transducer is vented to the atmosphere and pressure readings are made relative to atmospheric pressure. An absolute transducer measures the pressure at its location. The readings are then corrected for barometric pressure taken at the surface.
Range of tide	The difference in height between consecutive high and low waters. The mean range is the difference in height between mean high water and mean low water. The great diurnal range or diurnal range is the difference in height between mean higher high water and mean lower low water.
Relative mean sea level change	A local change in mean sea level relative to a network of benchmarks established in the most stable and permanent material available (bedrock, if possible) on the land adjacent to the tide station location. A change in relative mean sea level may be composed of both an absolute mean sea level change component and a vertical land movement change component, together.
S_2	Principal solar semi-diurnal constituent. This constituent represents the rotation of the Earth with respect to the Sun. Speed = 2T = 30.000,000,0° per solar hour.
Seiche	A stationary wave usually caused by strong winds and/or changes in barometric pressure. It is found in lakes, semi-enclosed bodies of water, and in areas of the open ocean. The period of a seiche in an enclosed rectangular body of water is usually represented by the formula: Period (T) = 2L / square root (gd) in which L is the length, d the average depth of the body of water, and g the acceleration of gravity.
Semi-diurnal	Having a period or cycle of approximately one-half of a tidal day. The predominant type of tide throughout the world is semi-diurnal, with two

© Crown 2025

	high waters and two low waters each tidal day. The tidal current is said to be semi-diurnal when there are two flood and two ebb periods each day. A semi-diurnal constituent has two maxima and two minima each constituent day, and its symbol is the subscript 2.
Shallow water constituent	A short-period harmonic term introduced into the formula of tidal (or tidal current) constituents to take account of the change in the form of a tide wave resulting from shallow water conditions. Shallow water constituents include the overtides and compound tides.
Slack water (Slack)	The state of a tidal current when its speed is near zero, especially the moment when a reversing current changes direction and its speed is zero. The term also is applied to the entire period of low speed near the time of turning of the current when it is too weak to be of any practical importance in navigation. The relation of the time of slack water to the tidal phases varies in different localities. For a perfect standing tidal wave, slack water occurs at the time of high and of low water, while for a perfect progressive tidal wave, slack occurs midway between high and low water.
Solar tide	1. The part of the tide that is due to the tide-producing force of the sun. 2. The observed tide in areas where the solar tide is dominant. This condition provides for phase repetition at about the same time each solar day.
Solid state	An electronic device composed of components with no moving parts – in this instance, using the electronic properties of solids, as in transistors, semi-conductors and integrated circuits.
Spring High Water	Same as Mean High Water Springs (MHWS). See Spring Tides.
Spring Low Water	Same as Mean Low Water Springs (MLWS). See Spring Tides and Mean Low Water Springs.
Spring tides	Tides of increased range or tidal currents of increased speed occurring semi-monthly as the result of the moon being new or full. The spring range (Sg) of tide is the average range occurring at the time of spring tides and is most conveniently computed from the harmonic constants. It is larger than the mean range where the type of tide is either semi- diurnal or mixed, and is of no practical significance where the type of tide is predominantly diurnal. The average height of the high waters of the spring tides is called Spring High Water or Mean High Water Springs (MHWS) and the average height of the corresponding low waters is called Spring Low Water or Mean Low Water Springs (MLWS).
Storm surge	The local change in the elevation of the ocean along a shore due to a storm. The storm surge is measured by subtracting the astronomic tidal elevation from the total elevation. It typically has a duration of a few hours. Since wind generated waves ride on top of the storm surge (and are not included in the definition), the total instantaneous elevation may greatly exceed the predicted storm surge plus astronomic tide. It is potentially catastrophic, especially on low-lying coasts with gently sloping offshore topography.
Telemeter	Transmit data to a distant receiving station via a telephone line or by telegraphic means.
Tidal characteristics	Principally, those features relating to the time, range, and type of tide.

© Crown 2025

Tidal constants	Tidal relations that remain practically constant for any particular locality. Tidal constants are classified as harmonic and non-harmonic. The harmonic constants consist of the amplitudes and epochs of the harmonic constituents, and the non-harmonic constants include the ranges and intervals derived directly from the high and low water observations.
Tidal current	A horizontal movement of the water caused by gravitational interactions between the Sun, Moon and Earth. The horizontal component of the particulate motion of a tidal wave. Part of the same general movement of the sea that is manifested in the vertical rise and fall called tide.
Tide	The periodic rise and fall of the water resulting from gravitational interactions between Sun, Moon and Earth. The vertical component of the particulate motion of a tidal wave. Although the accompanying horizontal movement of the water is part of the same phenomenon, it is preferable to designate this motion as tidal current.
Tide curve	A graphic representation of the rise and fall of the tide in which time is usually represented by the abscissa and height by the ordinate. For a semi-diurnal tide with little diurnal inequality, the graphic representation approximates a cosine curve.
Tide (water level) gauge	An instrument for measuring the rise and fall of the tide (water level).
Tide tables	Tables which give daily predictions of the times and heights of high and low waters. These predictions are usually supplemented by tidal differences and constants through which predictions can be obtained for numerous other locations.
Tsunami	A shallow water progressive wave, potentially catastrophic, caused by an underwater earthquake or volcano.
Universal Time (UTC)	Same as Greenwich Mean Time (GMT).
Z_0	Symbol recommended by the International Hydrographic Organisation to represent the elevation of mean sea level above chart datum.

Appendix D Data quality control process

The collected water level data is edited and quality coded in accordance with MHL quality control processes established for the *DCCEEW CPHR contract for the collection, archiving and dissemination of NSW coastal and flood data.* The approach exceeds the fundamental requirements of the *National Industry Guidelines for Hydrometric Monitoring* and other relevant guidelines such as the *Australian Tides Manual Special Publication No. 9*.

A numerical quality code is assigned to the dataset to describe the quality of individual observations and indicate the measurement uncertainty. **Figure D1** Overview of the water level data quality control process illustrates the two-step process applied by a data analyst and data reviewer:

1. Raw data adjustments using available in-field verification, calibration and secondary data type observations.
2. Comparison with independent data sources to enable its dissemination.

© Crown 2025

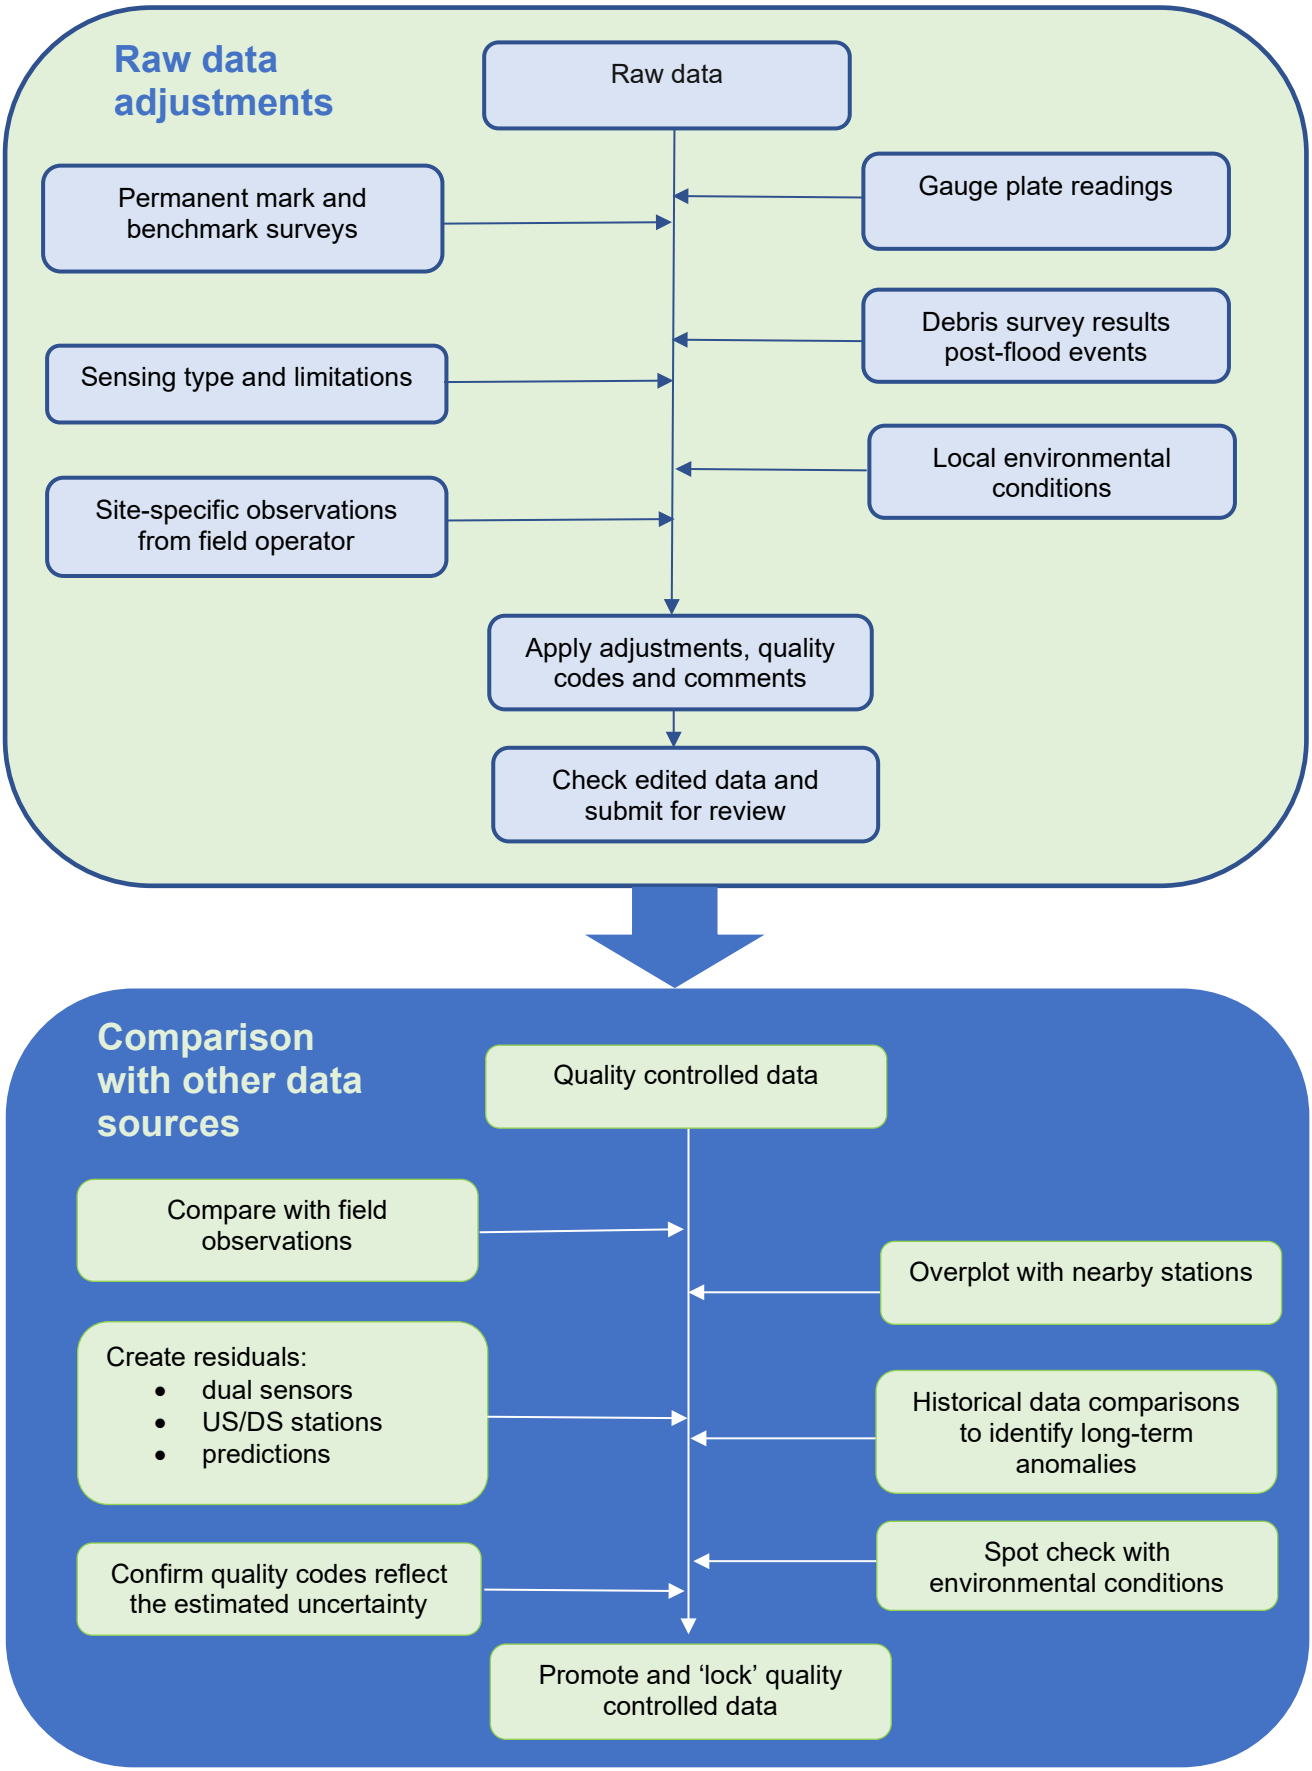

Figure D1 Overview of the water level data quality control process

© Crown 2025

A series of station maintenance procedures is periodically carried out to ensure data quality and maximise data recovery according to an agreed maintenance regime, including;

- scheduled site visits to obtain observer (live status) readings and verify logged data, as well as identify any site-specific monitoring issues, including but not limited to environmental conditions such as wind speed and direction, state of the tide (either ebb or flood flow), water conditions and amplitude of wave action at the site.
- Water level sensors are calibrated or verified as appropriate to the sensing type in accordance with MHL's work instructions.
- Station gauge plates are re-surveyed to available reference permanent marks and local benchmarks.

Based on the periodic observer readings, calibration/verification and survey results, data is edited and assigned a quality code. A raw dataset directly recovered from the logger is always retained as read-only and a secondary dataset contains the processed time series and associated quality coding. **Table D1** lists detailed data quality code descriptions.

Table D1 DCCEEW CPHR water level quality code descriptions

Quality code	Description	Post-processed uncertainty estimation*
55	Records processed to	±0.02 m
100	Data from previous MHL database, processed to	±0.02 m
105	Records processed to	±0.05 m
150	Uncoded – data not yet quality controlled	Raw data from the instrument with only preliminary quality checks performed
161, 162	Dry sensor	Sensor out of water with flow/with no flow
208	Records processed to greater than	>±0.05 m
1, 204, 205, 206, 207, 255	Data loss/data missing	

* A quality code is assigned based on infield status verification checks, survey and instrument calibrations including *an indication* of measurement uncertainty. Site-specific measurement uncertainty estimates with defined confidence limits can be quantified using statistical techniques on request.

Water level data editing may involve various standard hydrometric techniques including:

- Applying offsets when there is a sudden movement of the orifice in the water column, bank slump or deposition of silt during an event.
- Time shifts e.g. correction to eastern standard time (EST).
- Spike removal of false readings for known reasons.
- Linear transformations when drift over time occurs e.g. gradual deposition of silt, bio-fouling due to marine growth in lower estuarine areas, drift in sensor readings or gauge plate movement identified in surveys.
- Applying factors (vertical plane modification) due to change in calibration slope inputs or sensing is impeded by physical factors.

© Crown 2025

- Applying inversions due to incorrect device inputs when setting the level.
- Removing data that does not meet the required standards.
- Limited interpolation (gap filling) between logged points; this is generally no more than 1 hour in duration using typical exhibited patterns and not at the peak or trough of a tidal station (this technique is not used for sub-15 minute logging intervals).
- Applying quality codes and comments tagged to the time series data. Comments include a description of what edits and codes have been applied and why.

The data is only adjusted with thorough consideration and evaluation of sensor type and capability, observer readings, survey and calibration results, site-specific performance issues, environmental conditions, relationship with nearby stations and comparison with tidal predictions.

Prior to archiving, the quality controlled data are checked by the data analyst and then submitted to the data custodian for approval, which includes the following steps:

- Compare adjusted time series data with field operator gauge plate readings, post-flood debris line surveys and comments on conditions.
- Confirm survey adjustment or calibration results are applied as required.
- Overplot data with adjacent upstream and downstream river/estuary stations or ocean tide stations and inspect the data at a detailed scale to identify any gaps or anomalies.
- Any significant residuals between level data traces (water level absolute differences and changes in trend differences) can reveal datum shifts and drifts, survey issues, timing issues and erroneous readings. Data trace residuals are created and reviewed between:
  - dual sensors at the same site (if available)
  - upstream/downstream stations with residual inspection over short periods and long periods (e.g. specific events and 4 weeks, 6 months, 1 year, 5 years, 10 years).
  - the prediction (if available) and actual.
- Use secondary available environmental data such as rainfall and wind (speed and direction) to explain influences on water level measurement due to inflows and wind waves.
- Compare monthly means and accumulations with nearby stations over 10 to 20 years to identify any long-term trends that need to be corrected e.g. gauge plate and permanent mark subsidence from underground mining.

Once all issues are resolved, the quality controlled data is promoted and ‘locked’ such that no further changes can be applied.

The data should always be interpreted for its application taking into account the quality codes that have been applied. Advice from the data custodian should be sought to assist with any interpretation of data and quality codes, as well as any other required data quality descriptors.

© Crown 2025

Measurement uncertainty note:

At this stage, the water level measurement uncertainty is an indicative description only (quality code) applied to the post-processed data based on the aforementioned field techniques and site-specific environmental conditions. MHL is progressively refining measurement uncertainty estimates using *JCGM 100:2008 Guide to Expression of Uncertainty in Measurement (GUM)* approaches to strengthen quantifiable measurement uncertainty estimates within defined confidence limits.
